

Procedure-attributed feeding interruption rates are not comparable between ICUs

Attribution by record timestamps carries a large background rate — and that background differs by unit

What the indicator reports

29.0%

of feeding interruptions had
a procedure in window

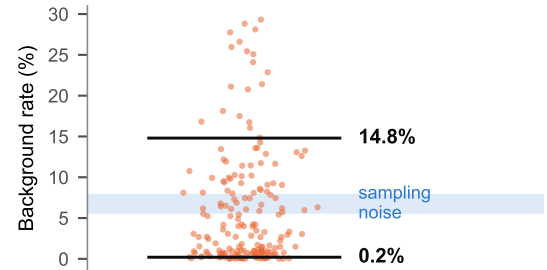

At matched control times

only
11.1 pp
excess

the same rule still fires: 53%
of attributions are coincidental

Across 182 hospitals

the background itself varies far
beyond sampling noise ($\tau = 7.08$ pp)

Report the background rate alongside any timestamp-derived attribution percentage, or the percentage is not interpretable between units.
